Concept Idea

Predictive Algorithm and Dynamic App Installation Model

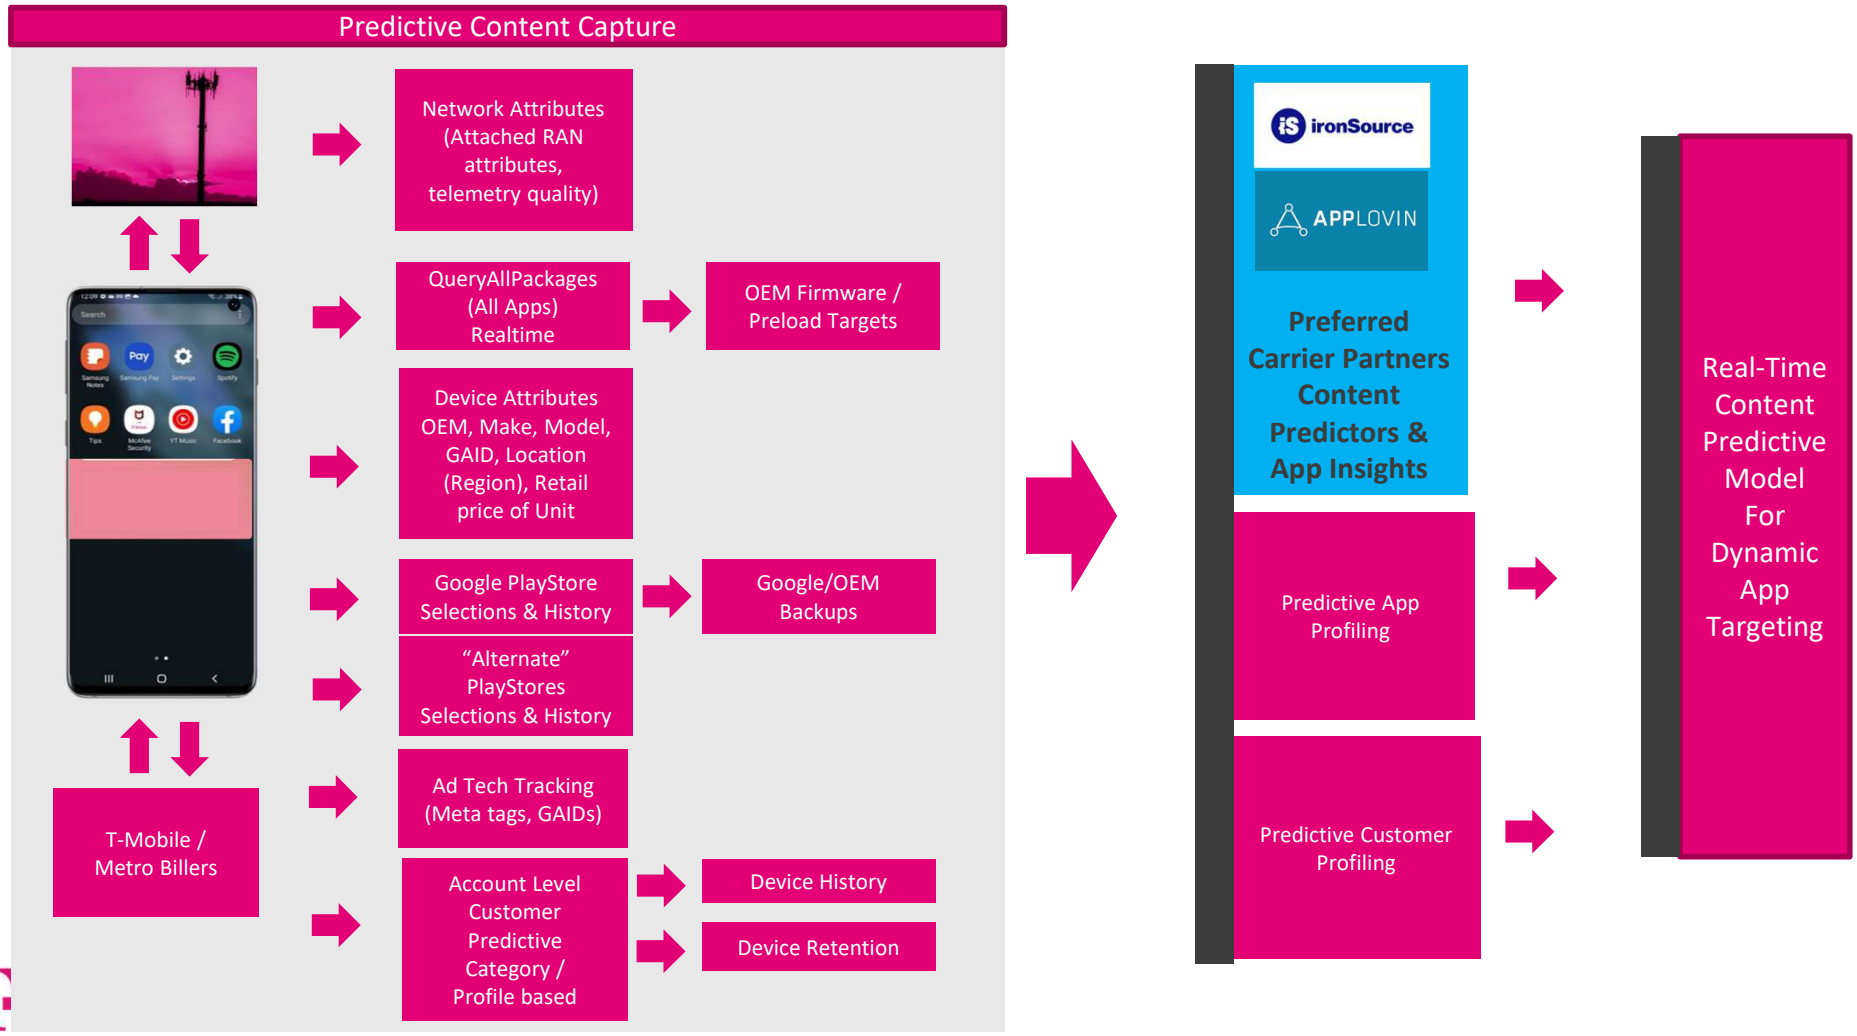
- As a T-Mobile customer with starting with a new device, my device should expertly predict what applications that I should 'desire' and want to consume as an Android user.

- As a T-Mobile, Metro, Assurance customer with a new device activation, my onboarding and new device experience will be better aligned with my device information, customer knowledge points, marketing insights, device history, and external supplier data points (Google Play Store history, device loaded apps).

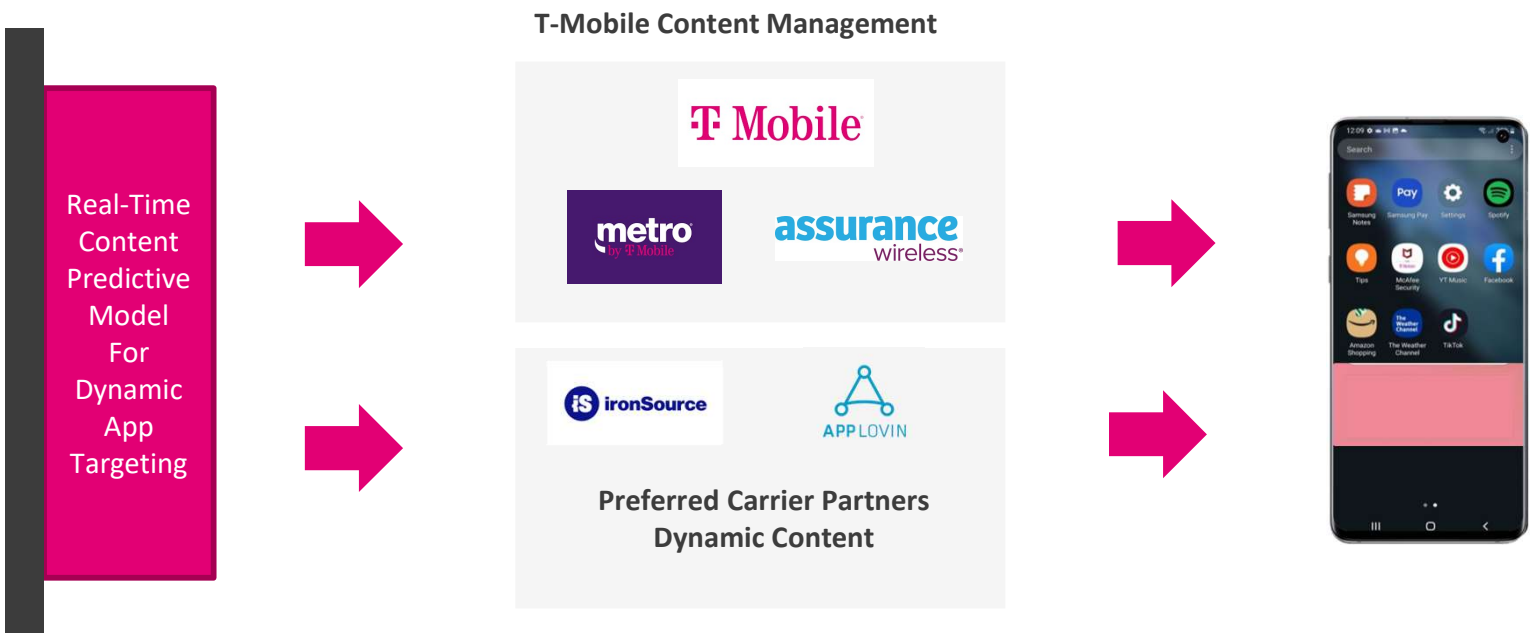
Technical Concept

- Prior to our T-Mobile content management dynamic application install process with a new device, T-Mobile will employ a 'layered cake' of data point aggregation and apply them to our own predictive algorithm and model for dynamically installing applications.
- This concept shall use a series of algorithms based on knowledge points on-device, off-device, and the user's entire technology ecosystem to predict what users will delightfully want new applications installed on their handset/tablets.
- Dynamic app installation does not use established norms of preloading through device firmware or a fixed firmware manifest. Rather, it uses real-time intelligence and content aggregation of the customer's ecosystem and applies the targeted content download with real-time logic during the device setup process.

Predictive Dynamic App Installation



Predictive Dynamic App Installation



Awareness: Because we as a carrier exist as a "entity in the middle" of all the ecosystems, we are in a unique position to aggregate our key data points and use our intelligence data to apply our own predictive algorithms for dynamic app installations.
